1. Intervals are presented in core length; true width will vary depending on the intersection angle of the hole with the targeted zone. Holes are generally planned to intersect vein structures as close perpendicular as possible and true widths are estimated to be 75%-85% of downhole widths. However, holes reported in this press release have been drilled obliquely to veins and true widths are estimated to be in the range of 50% of core length.
2. For known mineralized zones, intervals are based on geological observations and limited compositing of veins. Assays presented are not capped. Intercepts occur within geological confines of major zones but have not been correlated to individual vein domains at this time.
3. Vertical depth is measured from the surface to the mid-point of the reported interval.
4. High Grade Schist intercepts
